Grip Rehabilitation in Parkinson's Disease Using a Single-Point Sensor

Fictional Author A, Fictional Author B (Synthetic Demo Institute), 2026

Abstract

We find that the grip rehabilitation protocol did not improve hand function in Parkinson's patients measured with a single-point sensor. Data were collected in Dataset B.

1. Introduction

Parkinson's disease affects hand control. Simple sensors are cheap and easy to use.

2. Methodology

Parkinson's patients followed the grip rehabilitation protocol. A single-point sensor on the forearm recorded activity in Dataset B.

3. Results

Hand function scores did not improve in Parkinson's patients after the grip rehabilitation protocol. Grip strength showed no significant change in Parkinson's patients measured with a single-point sensor.

4. Discussion and Limitations

The sensor records one point only, so the full time course of muscle activation was not captured. Limitations include a small sample.

5. Conclusion

The grip rehabilitation protocol needs a better measurement approach in Parkinson's disease.
