Single-Point EMG Grip Assessment During Rehabilitation in Parkinson's Disease

Fictional Author A, Fictional Author B (Synthetic Demo Institute), 2026

Abstract

Results indicate that the grip rehabilitation protocol did not improve hand function in Parkinson's patients assessed with a single-point sensor. Data are in Dataset B.

1. Introduction

Grip training is widely used. Its value in Parkinson's disease is unclear.

2. Methodology

Parkinson's patients completed the grip rehabilitation protocol. Muscle signals came from a single-point sensor and are stored in Dataset B.

3. Results

Hand function scores did not improve in Parkinson's patients after the grip rehabilitation protocol. Grip strength showed no significant change in Parkinson's patients measured with a single-point sensor.

4. Discussion and Limitations

Limitations include a single centre. The protocol was not tested with other sensor types.

5. Conclusion

More work is needed before the protocol can be recommended for Parkinson's disease.
